

WORK LOG OF JUNE 13 2025

DANIEL R. BARRERO R.

1. GENERAL

- In `splitForest`, the typed value `(lrdr,krdr)` is matched against the typed value `plusAssoc j1 j2' j2''`.
- All relevant *code* written. Now dealing with compilation errors, mainly *coercion* for cases of type-level addition.
- `Proxy` is a polymorphic singleton type.

2. TYPE SIGNATURES AND FUNCTION EVALUATIONS

2.1. The type signature of the `splitForest` function is

```
splitForest :: forall f a b z q. SNat a -> SNat b ->
  Forest f q (a+b) ->
  (
    forall j j'. (j+j') ~ q =>
    (Forest f j a, Forest f j' b) -> z
  ) -> z
```

And the evaluation of its recursive case is given by

```
splitForest (SS (sl :: SNat l))
  (sk :: SNat k)
  (Cons (t :: f j1) (frt :: Forest f j2 (l+k)))
  =
splitForest sl sk frt $
  (
    \((lrdr :: Forest f j2' l),(krdr :: Forest f j2'' k)) ->
    case plusAssoc (j1 :: Proxy j1)
      (j2' :: Proxy j2')
      (j2'' :: Proxy j2'') of
    Dict -> c (Cons t lrdr , krdr)
  )
```

this can be visualized in the following picture:

2.2. The signature of the `Operad` typeclass is

```
class (Graded f) Operad where
  ident :: f One
  compose :: f n -> Forest f m n -> fm
```

And our instance of interest is the type `MoveTree`, which is parametrized by the `Nat` kind. Its signature is coupled with that of `Trees`, also parametrized by `Nat`. These signatures are

```
data MoveTree n where
  Leaf :: MoveTree One
  Fan :: Trees n -> MoveTree n

data Trees n where
  NilT :: Trees Z
  (:+) :: (Move, MoveTree a) -> Trees b -> Trees (a+b)
```

Therefore, the main challenge in making move trees an operad instance is defining the `compose` function, especially in the recursive case.

Here's an overview of the instantiation:

```
instance Operad MoveTree where
  ident = Leaf
  compose Leaf (Cons (t :: MoveTree m) Nil) =
    case plusZ :: Dict (m ~ (m + Z)) of Dict -> t
  compose (Fan ((mv, t) :+ ts)) frt =
    let ans = splitForest (grade t) (grade ts) frt lambda
        lambda = \(mst1, mst2) -> Fan ((mv, tree) :+ trees)
        tree = compose t mst1
        (Fan trees) = compose (Fan ts) mst2
    in ans
  compose _ _ = error "Composition_undefined!"
```

This depicts the composition arguments:

And this is a scheme of the composition's result:
